

R2. Model fitting and evaluation

2020 - 2021 Skagit River steelhead forecast.

Contents

Requirements	2
User inputs	11
Loading the fish data	12
Loading the covariates	13
Specifying models in JAGS	13
Beverton-Holt with covars and AR1 process errors (MA1 recruitment residuals). Here we will print out the model (contained in a separate text file)	13
Beverton-Holt with covars and AR1MA1 recruitment residuals	17
Beverton-Holt with covars and AR1 recruitment residuals	20
Fitting the models and generating the one year ahead forecasts	23
Model selection	24
Model selection via root mean squared error (RMSE) and mean absolute percent error (MAPE) model performance statistics.	24
Model Selection Via Approximate Leave-Future-Out Cross Validation	25
Model Selection Via <code>loo()</code> and <code>compare()</code> with full table of results.	27
Model Averaging and 2020 forecast	28
Compare sib adjusted forecasts with unadjusted	31

This is version 0.21.01.12.

Requirements

All analyses require the R software (v3.4.3) for data retrieval, data processing, and summarizing model results, and the JAGS software (v4.2.0) for Markov chain Monte Carlo (MCMC) simulation. Please note that some of the R code below may not work with older versions of JAGS due to some changes in the ways that arrays are handled.

We also need a few packages that are not included with the base installation of R, so we begin by installing them (if necessary) and then loading them.

```
if(!require("here")) {  
  install.packages("here")  
  library("here")  
}  
if(!require("readr")) {  
  install.packages("readr")  
  library("readr")  
}  
if(!require("rjags")) {  
  install.packages("rjags")  
  library("rjags")  
}  
if(!require("loo")) {  
  install.packages("loo")  
  library("loo")  
}  
if(!require("ggplot2")) {  
  install.packages("ggplot2")  
  library("ggplot2")  
}  
if(!require("coda")) {  
  install.packages("coda")  
  library("coda")  
}  
if(!require("shinystan")) {  
  install.packages("shinystan")  
  library("shinystan")  
}  
if(!require("R2jags")) {  
  install.packages("R2jags")  
  library("R2jags")  
}  
if(!require("dclone")) {  
  install.packages("dclone")  
  library("dclone")  
}  
if(!require("snow")) {  
  install.packages("snow")  
  library("snow")  
}  
if(!require("rstan")) {  
  install.packages("rstan")  
  library("rstan")  
}
```

```

if(!require("RColorBrewer")) {
  install.packages("RColorBrewer")
  library("RColorBrewer")
}
if(!require("gtools")) {
  install.packages("gtools")
  library("gtools")
}

## set directory locations
datadir <- here("data")
jagsdir <- here("jags")
analdir <- here("analysis")
savedir <- here("analysis/cache")

```

We also need a couple of helper functions.

```

## better round
Re2prec <- function(x, map = "round", prec = 1) {
  ## 'map' can be "round", "floor", or "ceiling"
  ## 'prec' is nearest value (eg, 0.1 means to nearest tenth; 1 gives normal behavior)
  if(prec<=0) { stop("\n\"prec\" cannot be less than or equal to 0") }
  do.call(map,list(x/prec))*prec
}

## wrapper function to fit JAGS models & rearrange output

```

User inputs

We begin by supplying values for the following parameters, which we need for model fitting and evaluation.

```
## first & last years of fish data
yr_first <- 1978
yr_last <- 2020

## min & max adult age classes
age_min <- 3
age_max <- 8

## years (if any) of age-comp to skip; see below
age_skip <- 0

## number of years ahead for run forecasts from the most recent year of data
n_fore <- 1

## number of recent year forecasts
n_forecasts <- 10

## first year of 1 step ahead forecast
yr_begin <- 2011

## last year of 1 step ahead forecast
yr_end <- 2020

## upper threshold for Gelman & Rubin's potential scale reduction factor (Rhat).
Rhat_thresh <- 1.1
```

Next we specify the names of three necessary data files containing the following information:

1. observed total number of adult spawners (escapement) by year;
2. observed age composition of adult spawners by year;
3. observed total harvest by year;

```
## 1. file with escapement data
## [n_yrs x 2] matrix of obs counts; 1st col is calendar yr
fn_esc <- "skagit_sthd_esc.csv"

## 2. file with age comp data
## [n_yrs x (1+A)]; 1st col is calendar yr
fn_age <- "skagit_sthd_age.csv"

## 3. file with harvest data
## [n_yrs x 2] matrix of obs catch; 1st col is calendar yr
fn_harv <- "skagit_sthd_catch.csv"
```

Loading the fish data

Here we load in the first three data files and do some simple calculations and manipulations. First the spawner data:

```
## escapement
dat_esc <- read_csv(file.path(datadir, fn_esc))
## years of data
dat_yrs <- dat_esc$year

## number of years of data
n_yrs <- length(dat_yrs)

## log of escapement
ln_dat_esc <- c(log(dat_esc$escapement), rep(NA, n_fore))
```

Next the age composition data:

```
## age comp data
dat_age <- read_csv(file.path(datadir, fn_age))
## num of age classes
A <- age_max - age_min + 1

# ## drop year col & first age_min+age_skip rows
# dat_age <- dat_age[-(1:(age_min+age_skip)), -1]
#
# ## add row(s) of NA's for forecast years
# if(n_fore > 0) {
#   dat_age <- rbind(dat_age,
#                     matrix(0, n_fore, A,
#                             dimnames = list(n_yrs+seq(n_fore),
#                                                  colnames(dat_age))))
# }
# ## total num of age obs by cal yr
# dat_age[, "sum"] <- apply(dat_age, 1, sum)
# ## row indices for any years with no obs age comp
# idx_NA_yrs <- which(dat_age$sum < A, TRUE)
# ## replace 0's in yrs w/o any obs with NA's
# dat_age[idx_NA_yrs, (1:A)] <- NA
# ## change total in yrs w/o any obs from 0 to A to help dmulti()
# dat_age[idx_NA_yrs, "sum"] <- A
# ## convert class
# dat_age <- as.matrix(dat_age)
```

And then the harvest data:

```
## harvest
dat_harv <- read_csv(file.path(datadir, fn_harv))
## drop year col & first age_max rows
# dat_harv <- c(dat_harv$catch, rep(NA, n_fore))
```

Loading the covariates

Our analysis investigates 5 covariates as possible drivers of the population's intrinsic growth rate:

1. Maximum river discharge in winter;
2. Minimum river discharge in summer;
3. North Pacific Gyre Oscillation;

All of the covariates are contained in the file `/data/skagit_sthd_covars.csv`. We will load and then standardize them to have zero-mean and unit-variance.

```
dat_cvrs <- read_csv(file.path(datadir, "skagit_sthd_covars.csv"))
## drop year col
# dat_cvrs <- dat_cvrs[,-1]
# ## transform the covariates to z-scores
# scl_cvrs <- as.matrix(scale(dat_cvrs))
# ## total number of covariates
# n_cov <- dim(dat_cvrs)[2]
```

Specifying models in JAGS

Now we can specify the model in JAGS. We evaluated a total of six different models, which we outline below, based on a beverton holt process model with covariates. Specifically, we evaluated three different methods to model recruitment residuals including a moving average process lagged 1 year (MA1), an auto-regressive moving average process lagged 1 year (AR1MA1), and an auto-regressive process lagged 1 year (AR1). In addition, we evaluated two methods for modeling maturation including a mean reverting process, and a random walk process.

Beverton-Holt with covars and AR1 process errors (MA1 recruitment residuals).
Here we will print out the model (contained in a separate text file)

```
processFile(file.path(jagsdir, "IPM_BH_cov_AR.txt"))

##

Fitting the models and generating the one year ahead forecasts

For the most recent 10 years (2011 - 2020), fit the model to data through year t-1 and generate a forecast for year t.

Before fitting the model in JAGS, we need to specify the MCMC control parameters.

```

## 1. MCMC control params
mcmc_ctrl <- list(
  chains = 4,
  length = 200000, #5e5,

```

```

burn = 100000, #2e5,
thin = 100 #400
)
## total number of MCMC samples after burnin
mcmc_samp <- mcmc_ctrl$length*mcmc_ctrl$chains/mcmc_ctrl$thin

## fit or load models
models=c("IPM_BH_cov_MA1_AR1",
         "IPM_BH_cov_AR",
         "IPM_BH_cov_AR_resid",
         "IPM_BH_cov_MA1_AR1_age",
         "IPM_BH_cov_AR_age",
         "IPM_BH_cov_AR_resid_age"
        )
n_mods<-length(models)
mod_fits <- fit_load_mods(models=models)

```

Model selection

We evaluated model performance following three separate approaches outlined below.

Model selection via root mean squared error (RMSE) and mean absolute percent error (MAPE) model performance statistics.

```

tot_mods <- n_forecasts*n_mods

# get escapement data
dat_esc_forecast <- dat_esc[which(dat_esc$year %in% seq(yr_begin, yr_end, 1)),]

## get harvest data
dat_harv_forecast <- dat_harv[which(dat_harv$year %in% seq(yr_begin, yr_end, 1)),]

## observed terminal run size
obs_trs <- dat_esc_forecast$escapement + dat_harv_forecast$catch

pred_trs <- NULL
for(n in 1:n_mods){
  #n <- 1
  pred_esc <- NULL
  for(i in 1:(n_forecasts)){
    #i <- 1
    mod_res<-NULL
    mod_res<-as.matrix(readRDS(file.path(savedir, paste0(models[n], "_y", i, ".rds"))))
    p_dat <- mod_res[,grep("Sp", colnames(mod_res))]
    p_dat <- round(median(p_dat[,dim(p_dat)[2]]))

    pred_esc[i] <- p_dat
  }
}

```

```

}

pred_trs_mod <- pred_esc + 1#dat_harv_forecast$catch #you don't need to add catch in because it is
pred_trs <- cbind(pred_trs,pred_trs_mod)

Calculating Stacking Weights (finding model averaging weights based on one-step-ahead performance of weighted average models). This is an experimental calculation of stacking weights based on linear combinations of model forecasts to optimize one step ahead RMSE, MSA, or MAPE. . . it is not ready for prime time yet. An alternative is to figure out how to use methods similar to “stacking weights” here for LFOIC: [link](#)

```
stack_weights<-find_stack_weights(tau=1,
                                  n=10000,
                                  metric="MSA",
                                  initial_weights=rep(1/length(models),length(models)),
                                  preds=pred_trs,
                                  obs=obs_trs
                                  )
stacking_weights<-as.vector(round(unlist(stack_weights[[1]]),4))
model_selection$stacking_weights<-stacking_weights
```

Model Selection Via loo() and compare() with full table of results.

Note that `elpd_diff` will be negative (positive) if the expected predictive accuracy for the first (second) model is higher.

```
LOOIC <- vector("list", n_mods)
## extract log densities from JAGS objects
for(i in 1:n_mods) {
  #i <- 1
  ## convert mcmc.list to matrix
  tmp_lp <- as.matrix(readRDS(file.path(savedir,paste0(models[i],"_y",11,".rds"))))
  ## extract pointwise likelihoods
```

```

```

It looks like applying the sibling adjustment improved the forecast for only 2 of the 10 years and resulted in poorer performance overall.
