This is version 0.20.12.16.	

## Requirements

All analyses require the R software (v3.4.3) for data retrieval, data processing, and summarizing model results, and the JAGS software (v4.2.0) for Markov chain Monte Carlo (MCMC) simulation. Please note that some of the R code below may not work with older versions of JAGS due to some changes in the ways that arrays are handled.

We also need a few packages that are not included with the base installation of R, so we begin by installing them (if necessary) and then loading them.

```
if(!require("here")) {
  install.packages("here")
  library("here")
if(!require("readr")) {
  install.packages("readr")
  library("readr")
}
if(!require("rjags")) {
  install.packages("rjags")
  library("rjags")
}
if(!require("loo")) {
  install.packages("loo")
  library("loo")
if(!require("ggplot2")) {
  install.packages("ggplot2")
  library("ggplot2")
}
if(!require("coda")) {
  install.packages("coda")
  library("coda")
}
if(!require("shinystan")) {
  install.packages("shinystan")
  library("shinystan")
}
if(!require("R2jags")) {
  install.packages("R2jags")
  library("R2jags")
if(!require("dclone")) {
  install.packages("dclone")
  library("dclone")
}
if(!require("snow")) {
  install.packages("snow")
  library("snow")
}
## set directory locations
datadir <- here("data")</pre>
jagsdir <- here("jags")</pre>
analdir <- here("analysis")</pre>
savedir <- here("analysis/cache")</pre>
```

We also need a couple of helper functions.

```
## better round
Re2prec <- function(x, map = "round", prec = 1) {
    ## 'map' can be "round", "floor", or "ceiling"</pre>
```

```
## 'prec' is nearest value (eg, 0.1 means to nearest tenth; 1 gives normal behavior)
  if(prec<=0) { stop("\"prec\" cannot be less than or equal to 0") }</pre>
  do.call(map,list(x/prec))*prec
}
## wrapper function to fit JAGS models & rearrange output
fit_jags <- function(model, data, params, inits, ctrl, dir = jagsdir) {</pre>
  jm <- jags.model(file.path(jagsdir, model),</pre>
                    data,
                    inits.
                    ctrl$chains,
                    ctrl$burn,
                    quiet = TRUE)
  return(coda.samples(jm, params, ctrl$length, ctrl$thin))
#alternative wrapper to fit model in parallel; one chain per core
fit_jags2<-function(model,data,params,inits,ctrl,dir=jagsdir){</pre>
  # jm<-jaqs.parallel(data=data,</pre>
                       inits=inits.
  #
                       parameters.to.save=params,
  #
                       model.file = file.path(jagsdir, model),
                       n.chains = ctrl $chains,
                       n.iter = ctrl$length,
  #
                       n.burnin = ctrl$burn,
  #
                       n.thin = ctrl\$thin,
                       DIC = TRUE.
  # )
  # write.csv(jm$BUGSoutput$summary,file.path(savedir,paste(model,".csv",sep="")))
  # jm<-jags.parfit(data=data,</pre>
                       inits=inits,
  #
                       parameters.to.save=params,
  #
                       model.file = file.path(jagsdir, model),
  #
                       n.chains = ctrl\$chains,
                       n.iter = ctrl$length,
                       n.burnin = ctrl\$burn,
                       n.thin = ctrl\$thin,
  #
  #
                       DIC = TRUE,
  # )
  # return(as.mcmc.list(as.mcmc(jm)))
  cl <- makeCluster(3, type = "SOCK")</pre>
  inits2 <- jags.fit(data=data,</pre>
                      params=params,
                      model=file.path(jagsdir, model),
                      inits=inits,
                      n.chains=ctrl$chains,
                      n.adapt = 0,
                      n.update = 0,
                      n.iter = 0)$state(internal = TRUE)
  jm <- jags.parfit(cl=cl,</pre>
                     data = data,
                     params = params,
                     model = file.path(jagsdir, model),
```

## User inputs

We begin by supplying values for the following parameters, which we need for model fitting and evaluation.

```
## first & last years of fish data
yr_frst <- 1978
yr_last <- 2020

## min & max adult age classes
age_min <- 3
age_max <- 8
## years (if any) of age-comp to skip; see below
age_skip <- 0

## number of years ahead for run forecasts
n_fore <- 1

## number of recent year forecasts
n_forecasts <- 10

## upper threshold for Gelman & Rubin's potential scale reduction factor (Rhat).
Rhat_thresh <- 1.1</pre>
```

Next we specify the names of three necessary data files containing the following information:

- 1. observed total number of adult spawners (escapement) by year;
- 2. observed age composition of adult spawners by year;
- 3. observed total harvest by year;

```
## 1. file with escapement data
## [n_yrs x 2] matrix of obs counts; 1st col is calendar yr
fn_esc <- "skagit_sthd_esc.csv"

## 2. file with age comp data
## [n_yrs x (1+A)]; 1st col is calendar yr
fn_age <- "skagit_sthd_age.csv"

## 3. file with harvest data
## [n_yrs x 2] matrix of obs catch; 1st col is calendar yr
fn_harv <- "skagit_sthd_catch.csv"</pre>
```

### Loading the fish data

Here we load in the first three data files and do some simple calculations and manipulations. First the spawner data:

```
## escapement
dat_esc <- read_csv(file.path(datadir, fn_esc))
## years of data
dat_yrs <- dat_esc$year

## number of years of data
n_yrs <- length(dat_yrs)

## log of escapement
ln_dat_esc <- c(log(dat_esc$escapement),rep(NA,n_fore))</pre>
```

Next the age composition data:

```
## age comp data
dat_age <- read_csv(file.path(datadir, fn_age))</pre>
## num of age classes
A <- age_max - age_min + 1
# ## drop year col & first age_min+age_skip rows
# dat_age <- dat_age[-(1:(age_min+age_skip)),-1]</pre>
# ## add row(s) of NA's for forecast years
# if(n_fore > 0) {
   dat_age <- rbind(dat_age,</pre>
                      matrix(0, n_fore, A,
#
                              dimnames = list(n_yrs+seq(n_fore),
#
                                              colnames(dat_aqe))))
# }
# ## total num of age obs by cal yr
# dat_age[,"sum"] <- apply(dat_age, 1, sum)</pre>
# ## row indices for any years with no obs age comp
# idx_NA_yrs <- which(dat_age$sum<A, TRUE)</pre>
# ## replace 0's in yrs w/o any obs with NA's
\# dat_age[idx_NA_yrs,(1:A)] \leftarrow NA
# ## change total in yrs w/o any obs from 0 to A to help dmulti()
\# dat_age[idx_NA_yrs,"sum"] \leftarrow A
# ## convert class
# dat_age <- as.matrix(dat_age)</pre>
```

And then the harvest data:

```
## harvest
dat_harv <- read_csv(file.path(datadir, fn_harv))
## drop year col & first age_max rows
#dat_harv <- c(dat_harv$catch,rep(NA,n_fore))</pre>
```

### Loading the covariates

Our analysis investigates 5 covariates as possible drivers of the population's instrinic growth rate:

- 1. Maximum river discharge in winter;
- 2. Minimum river discharge in summer;
- 3. North Pacific Gyre Oscillation;

All of the covariates are contained in the file /data/skagit\_sthd\_covars.csv. We will load and then standardize them to have zero-mean and unit-variance.

```
dat_cvrs <- read_csv(file.path(datadir, "skagit_sthd_covars.csv"))
## drop year col
# dat_cvrs <- dat_cvrs[,-1]
# ## transform the covariates to z-scores
# scl_cvrs <- as.matrix(scale(dat_cvrs))
# ## total number of covariates
# n_cov <- dim(dat_cvrs)[2]</pre>
```

## Specifying models in JAGS

Now we can specify the model in JAGS. We fit a total one model, which we outline below, based on a beverton holt process model with covariates.

#### Beverton-Holt with covars

```
cat("
    model {
    ##-----
    ## PRIORS
    ## alpha = intrinsic productivity
    alpha ~ dnorm(0,0.001) T(0,);
    mu_BH_a <- log(alpha);</pre>
    E_BH_a <- mu_BH_a + sigma_r/(2 - 2*phi^2);</pre>
    ## strength of dens depend
    beta_inv ~ dnorm(0, 1e-9) T(0,);
    beta <- 1/beta_inv;</pre>
    ## covariate effects
    for(i in 1:n_cov) { gamma[i] ~ dnorm(0,0.01) }
    ## AR(1) coef for proc errors
    #phi ~ dunif(-0.999,0.999);
    #phi <- 0;</pre>
    phi_prior ~ dbeta(2,2);
    phi <- phi_prior*2-1;</pre>
```

```
#phi ~ dunif(0,0.999);
